

How to manage your dental procedure along with your nursing schedule

It is not known whether local anesthetic drugs are excreted in human milk. Because many drugs are excreted in human milk caution should be exercised when local anesthetics are administered to a nursing woman. The general rule of thumb is that 1% of medication is transferred

Local anesthesia is absorbed through the tissues into the blood stream where it is broken down or metabolized primarily in the liver. It is subsequently reabsorbed in the kidney.

Since most of the anesthetic and its metabolites are eliminated within 30 hours use this information & discretion when caring for your child
